

**Lecture 12**

**Context Bounding Checkers I**

Zvonimir Rakamarić  
University of Utah

# Announcements

- ▶ Dafny homework assignment due on Wed (before class)
- ▶ Project proposal due on Wed (before class)
- ▶ Message me if you would like to discuss your project before Wed
- ▶ Posting papers on Canvas accompanying the material covered in lectures
  - ▶ Try to read them

# Huge Number of Thread Schedules

- ▶ Concurrent program with  $n$  threads where each thread has  $k$  instructions has

$$(n \cdot k)! / (k!)^n \geq (n!)^k$$

interleavings

- ▶ Exponential in both  $n$  and  $k$ !
- ▶ Example: 5 threads with 5 instruction each

$$\begin{aligned} 25! / 5!^5 &= 6.2336074e+14 \\ &= 623 \text{ trillion interleavings} \end{aligned}$$

# Java Path Finder (JPF)

- ▶ Program checker for Java
- ▶ Properties to be verified
  - ▶ Program assertions
  - ▶ LTL properties
- ▶ Depth-first and breadth-first search, heuristics
  - ▶ Uses static analysis techniques to improve the efficiency of the search
- ▶ Requires a complete Java program
  - ▶ Cannot handle native code

# Combating State Space Explosion

- ▶ Symmetry reduction
  - ▶ Search equivalent states only once
- ▶ Partial order reduction
  - ▶ Do not search thread interleavings that generate equivalent behavior
- ▶ Static analyses
  - ▶ Reduce state space using static analyses
- ▶ User-provided restrictions
  - ▶ Manually bound variable domains, array sizes,...

# Symmetry Reduction in JPF

- ▶ Order in which classes are loaded shouldn't effect the state
  - ▶ There is a canonical ordering of classes
- ▶ Location of dynamically allocated heap objects shouldn't effect the state
  - ▶ If we store the memory location as the state, then we can miss equivalent states which have different memory layouts
  - ▶ Store some information about the new statements and the number of times they are executed

# Simple Symmetry Example

```
int x, y;
```

```
Foo a, b;
```

Thread 1:

1) a = new Foo();

2) x = 1;

3) y = 2;

4) x++;

5) y++;

Thread 2:

5) b = new Foo();

6) y = 3;

7) x = 2;

8) y++;

9) x++;

# Partial Order Reduction

- ▶ Statements of concurrently executing threads can generate many different interleavings
  - ▶ All these different interleavings are allowable behavior of the program
- ▶ Model checker checks all possible interleavings for errors
  - ▶ But different interleavings may generate equivalent behaviors
- ▶ Partial order reduction
  - ▶ It is sufficient to check just one representative interleaving

# Simple POR Example

```
int x, y;
```

Thread 1:

```
int a;
```

```
1) a = 5;
```

```
2) a++;
```

```
3) x = 1;
```

```
4) y = 2;
```

```
5) x++;
```

```
6) y++;
```

Thread 2:

```
int b;
```

```
5) b = 10;
```

```
6) b--;
```

```
7) y = 3;
```

```
8) x = 2;
```

```
9) y++;
```

```
10) x++;
```

# Static Analysis in JPF

- ▶ Using static analysis techniques to reduce the state space
  - ▶ Slicing
  - ▶ Partial evaluation

# Static Analysis in JPF

## ▶ Slicing

- ▶ Remove program parts with no effect on the slicing criterion
  - ▶ A slicing criterion could be a program point
- ▶ Program slices are computed using dependency analysis

## ▶ Partial evaluation

- ▶ Propagate constant values and simplify expressions

# User-Provided Restrictions

- ▶ To improve scalability, users can restrict domains of variables, sizes of arrays,...
- ▶ Restrictions under-approximate program behaviors
  - ▶ May result in missed errors
  - ▶ Still useful in finding bugs

# This Time

- ▶ Context-bounded verification of concurrent programs

# Context-Bounded Verification

slides acknowledgements: Shaz Qadeer, Madan Musuvathi

# Context-Bounded Verification

- ▶ Many subtle concurrency errors are manifested in executions with few context switches
- ▶ Analyze all executions with few context switches

# Context-Bounded Reachability Problem

- ▶ An execution is  $c$ -bounded if every thread has at most  $c$  contexts
- ▶ Does there exist a  $c$ -bounded execution from a state  $S$  to a state  $E$ ?

# CB Reachability is NP-Complete

## ► Membership in NP

- Witness is an initial state and  $n \cdot c$  sequences each of length at most  $|L \times G|$

$n = \#$  of threads,  $c = \#$  of contexts

$L = \#$  of program locations,  $G = \#$  of global states

## ► NP-hardness

- Reduction from the CIRCUIT-SAT problem

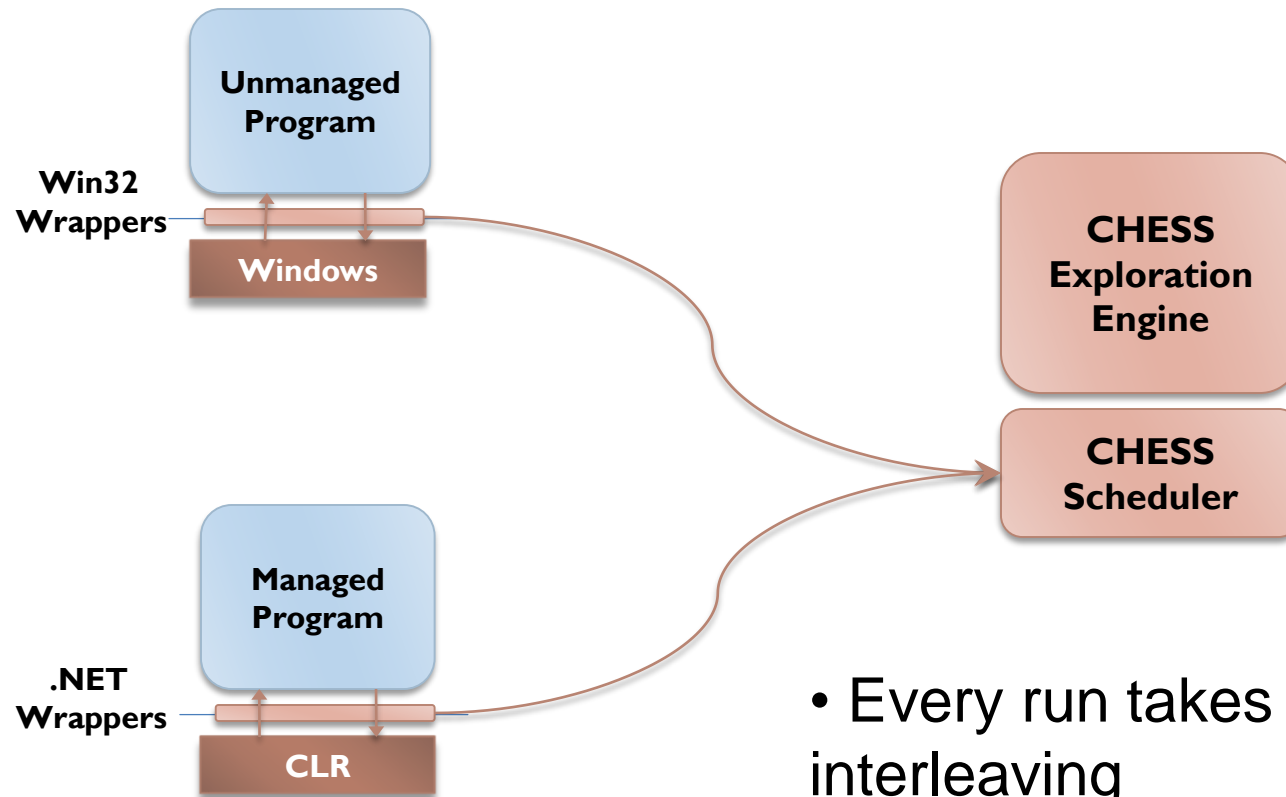

# Complexity of Safety Verification

	Unbounded	Context-bounded
Finite-state systems	PSPACE complete	NP-complete
Pushdown systems	Undecidable	NP-complete

# CHESS: Systematic Testing for Concurrency

- ▶ CHESS is a user-mode scheduler
- ▶ Controls all scheduling nondeterminism
  - ▶ Replace the OS scheduler
- ▶ Guarantees:
  - ▶ Every program run takes a different thread interleaving
  - ▶ Reproduce the interleaving for every run

# CHESS Architecture

- Every run takes a different interleaving
- Reproduce the interleaving for every run

# State-Space Explosion

- ▶ Number of executions is  $O(n^{nk})$
- ▶ Exponential in both  $n$  and  $k$ 
  - ▶ Typically:  $n < 10$ ,  $k > 1000$
- ▶ Limits scalability to large programs

**Goal:** Scale CHESS to large programs (large  $k$ )

# Preemption-Bounding

- ▶ Prioritize executions with small # of preemptions
- ▶ Two kinds of context switches:
  - ▶ Preemptions – forced by the scheduler
    - ▶ E.g., time-slice expiration
  - ▶ Non-preemptions – a thread voluntarily yields
    - ▶ E.g., blocking on an unavailable lock, thread end

# Preemption-Bounding in CHESS

- ▶ The scheduler has a budget of  $c$  preemptions
  - ▶ Nondeterministically choose the preemption points
- ▶ Resort to non-preemptive scheduling after  $c$  preemptions
- ▶ Once all executions explored with  $c$  preemptions
  - ▶ Try with  $c+1$  preemptions

# Property 1: Polynomial Bound

- ▶ Terminating program with fixed inputs and deterministic threads
  - ▶  $n$  threads,  $k$  steps each,  $c$  preemptions
- ▶ Number of executions  $\leq {}_{nk}C_c * (n+c)!$   
 $= O((n^2k)^c * n!)$
- ▶ Exponential in  $n$  and  $c$ , but not in  $k$ !

- Choose  $c$  preemption points
- Permute  $n+c$  atomic blocks

## Property 2: Simple Error Traces

- ▶ Finds smallest number of preemptions to the error
- ▶ Number of preemptions better metric of error complexity than execution length

## Property 3: Coverage Metric

- ▶ If search terminates with preemption-bound of  $c$ , then any remaining error must require at least  $c+1$  preemptions
- ▶ Intuitive estimate for
  - ▶ The complexity of the bugs remaining in the program
  - ▶ The chance of their occurrence in practice

# Property 4: Many Bugs with Few Preemptions

Program	kLOC	Threads	Preemptions	Bugs
<b>Work-Stealing Queue</b>	1.3	3	2	3
<b>CDS</b>	6.2	3	2	1
<b>CCR</b>	9.3	3	2	2
<b>ConcRT</b>	16.5	4	3	4
<b>Dryad</b>	18.1	25	2	7
<b>APE</b>	18.9	4	2	4
<b>STM</b>	20.2	2	2	2
<b>PLINQ</b>	23.8	8	2	1
<b>TPL</b>	24.1	8	2	9

# Coverage vs Preemption-Bound
